KEEP IT LOCAL: DRINK TAP WATER!

Where does your tap (drinking) water come from?

**Well #1** is located off of Holtshire Rd. (and is used for emergencies only).

**Wells #2 & 2A** are located off of West River St. (Magee Meadows).

**Well #3** is located off of Daniel Shays Highway (Route 202).

We also have an emergency interconnection with the Town of Athol on Brookside Rd.

What’s on Tap for 2019?

- Water storage tanks exterior coatings and safety upgrades
- Dam maintenance
- Town Wide Hydrant/Valve maintenance and repairs.
- Well #1: Continued testing to provide a replacement source.

*Note: Field work may cause delays and inconvenience, your patience is greatly appreciated.*

Lead and Copper Detections

If present, elevated levels of lead can cause serious health problems, especially for pregnant women and young children. Lead in drinking water is primarily from materials and components associated with service lines and home plumbing. Orange Water Department (OWD) is responsible for providing high quality drinking water, but cannot control the variety of materials used in plumbing components. When your water has been sitting for several hours, you can minimize the potential for lead exposure by flushing your tap for 30 seconds to 2 minutes before using water for drinking or cooking. If you are concerned about lead in your water, you may wish to have your water tested. Information on lead in drinking water, testing methods, and steps you can take to minimize exposure is available from the Safe Drinking Water Hotline or at [http://www.epa.gov/safewater/lead](http://www.epa.gov/safewater/lead).

Tips For Saving Water

- Visit our website for money-saving water conservation ideas.
- Visit our office for a free water conservation kit.
- Pay attention to leaky toilets and fixtures. Repair as needed.
- If your water bill is unusually high or you suspect a leak in your outdoor water service line, please contact us right away so that we can assess the situation and reduce the likelihood of wasteful leaks.

Note: Our water quality testing results for 2018 are provided on the enclosed table.
Health Effects of Some Contaminants

Drinking water, including bottled water, may reasonably be expected to contain at least small amounts of some contaminants. The presence of contaminants does not necessarily indicate that water poses a health risk. More information about contaminants and potential health effects can be obtained by calling the U.S. Environmental Protection Agency (EPA) Safe Drinking Water Hotline (1-800-426-4791).

Sources of Drinking Water and Drinking Water Contaminants

Sources of drinking water (both tap water and bottled water) include rivers, lakes, streams, ponds, reservoirs, springs, and wells. As water travels over the surface of land or through the ground, it dissolves naturally occurring minerals, and, in some cases, radioactive material, and can pick up substances resulting from the presence of animals or from human activity. Our water system makes every effort to provide you with safe and pure drinking water. To improve the quality of the water delivered to you, we chemically treat the water to reduce lead and copper concentrations, and, we add a disinfectant to protect you against microbial contaminants. The water quality of our system is constantly monitored by us and MassDEP to determine the effectiveness of existing water treatment and to determine if any additional treatment is required.

Contaminants that may be present in source water include:

- **Microbial contaminants**, such as viruses and bacteria, which may come from sewage treatment plants, septic systems, agricultural livestock operations and wildlife.
- **Inorganic contaminants**, such as salts and metals which can be naturally-occurring or result from urban storm water runoff, industrial or domestic wastewater discharges, oil and gas production, mining and farming.
- **Pesticides and herbicides**, which may come from a variety of sources such as agriculture, urban storm water runoff and residential uses.
- **Organic chemical contaminants**, including synthetic and volatile organic chemicals which are by-products of industrial processes and petroleum production and can also come from gas stations, urban storm water runoff and septic systems.
- **Radioactive contaminants**, which can be naturally occurring or be the result of oil and gas production and mining activities.

In order to ensure that tap water is safe to drink, the MA Department of Environmental Protection (DEP) and EPA prescribe regulations that limit the amount of certain contaminants in water provided by public water systems. The Food and Drug Administration (FDA) and the MA Department of Public Health (DPH) regulations establish limits for contaminants in bottled water that must provide the same protection for public health.

For Your Information

The Water Dept. will be flushing most of the hydrants in town during normal working hours in the spring and fall. The flushing schedule will be posted in the newspaper and on the Town’s web site (www.townoforange.org). Flushing is very important to maintain good water quality and fire flow. We apologize for any temporary inconvenience.
What is a “cross-connection”? 
A cross-connection is a permanent or temporary piping arrangement which can allow your drinking water to be contaminated if backflow occurs.

Cross connections can occur in many residential, commercial and institutional settings and are often associated with: Boilers, air conditioning units, fire sprinklers, lawn irrigation, solar heaters, chemical sprayers/storage, auxiliary wells, lab equipment, submerged piping, cooling towers, soda fountains, mop sinks, heat exchangers, soap injectors, etc.

What is “backflow”? 
Backflow is when the water flows in the opposite direction from normal. With the direction of flow reversed, due to a change in pressures, contaminants may enter the town’s water system through cross-connections.

A potentially hazardous cross-connection occurs every time someone uses a garden hose sprayer to apply insecticides or herbicides to their lawn. Another cross-connection occurs when someone uses a garden hose to clear a stoppage in their sewer line. Without a backflow prevention device between your hose and hose bibb (spigot or outside faucet), the contents of the hose and anything it is connected to can backflow into the piping system and contaminate drinking water throughout the town.

Backflows and cross-connections are serious plumbing problems. They can cause sickness and even death. However, they can be avoided by the use of proper protection devices such as air gaps, pressure vacuum breakers, reduced pressure valves and double check valves. The type of device used depends on the degree of health hazard. For example, hose-bibb vacuum breakers (photo below) are simple, inexpensive and easy to find, and should be installed on every home spigot.

More complex backflow prevention devices are often needed for businesses and municipal facilities. These devices are tested on an annual or semi-annual basis. If you own one or more of these devices, please refer to State Regulation 310 CMR22.22 to fully understand your maintenance responsibilities.

For more information on cross-connection control and backflow prevention for your home or business, please contact the Orange Water Department at 978-544-1115.
Reportable detections of contaminants from the most recent annual round of testing done within the last five years in accordance with the regulations are included below. We are committed to providing you the best water quality available and encourage you to contact us with any questions. Your drinking water continues to meet all applicable state and federal health standards.

**Maximum Contaminant Level or MCL:** The highest level of a contaminant that is allowed in drinking water. MCLs are set as close as possible to MCLGs (see below) as feasible using the best available technology.

**Maximum Contaminant Level Goal or MCLG:** The level of a contaminant in drinking water below which there is no known or expected health risk. MCLGs allow for a margin of safety.

**Action Level or AL:** The concentration of a contaminant that, if exceeded, triggers treatment or other requirements, which a water system must follow.

**90th Percentile:** Out of every 20 homes tested, 18 were at or below this level.

**Maximum Residual Disinfection Level (MRDL):** The highest level of a disinfectant allowed in drinking water. There is convincing evidence that addition of a disinfectant is necessary for control of microbial contaminants.

**Maximum Residual Disinfection Level Goal (MRDLG):** The level of a drinking water disinfectant below which there is no known or expected risk to health. MRDLGs do not reflect the benefits of use of disinfectants to control microbial contaminants.

**Treatment Technique (TT):** A required process intended to reduce the level of a contaminant in drinking water.

**Units:** Milligrams/Liter or mg/L = parts per million, Micrograms/Liter or ug/L = parts per billion, Picocuries/Liter or pCi/L = a measure of radioactivity, ND = Not Detected.

(1) Nitrate in drinking water at levels above 10 ppm is a health risk for infants of less than six months of age. High nitrate levels in drinking water can cause blue baby syndrome. Nitrate levels may rise quickly for short periods of time because of rainfall or agricultural activity. If you are caring for an infant, you should ask for advice from your health care provider. The highest collected nitrate level was less than 10 ppm.

(2) Sodium sensitive individuals, such as those experiencing hypertension, kidney failure, or congestive heart failure, should be aware of sodium levels exceeding the state chronic exposure guideline of 20 mg/L (where exposures are being carefully controlled).

(3) Some older homes have lead joints or pipes in their plumbing systems. When water is allowed to remain in these systems for a period of time, lead can dissolve into the water. If you are concerned about your home’s water, you may elect to have it tested.

(4) Manganese is a naturally occurring mineral found in rocks, soil and groundwater, and surface water. Manganese is necessary for proper nutrition and is part of a healthy diet, but can have undesirable effects on certain sensitive populations at elevated concentrations. The United States Environmental Protection Agency (EPA) and MassDEP have set aesthetics-based Secondary Maximum Contaminant Level (SMCL) for manganese of 50 ug/L (micrograms per liter), or 50 parts per billion. In addition, MassDEP’s Office of Research and Standards (ORS) has set a drinking water guideline for manganese (ORSG), which closely follows the EPA public health advisory for manganese. Drinking water may naturally have manganese and, when concentrations are greater than 50 mg/L, the water may be discolored and taste bad. Over a lifetime, EPA recommends that people drink water with manganese levels less than 300 ug/L and over the short term, EPA recommends that people limit their consumption of water with levels over 1000 ug/L, primarily due to concerns about possible neurological effects. Children up to 1 year of age should not be given water with manganese concentrations over 300 ug/L, nor should formulas for infants be made with that water for longer than 10 days. The ORSG differs from the EPA’s health advisory because it expands the age group to which a lower manganese concentration applies: children less than 6 months of age to children up to 1 year of age to address concerns about children’s susceptibility to manganese toxicity. See: EPA Drinking Water Health Advisory for Manganese http://www.epa.gov/safewater/ccl/pdfs/reg determine1/support cc1 magnese dwreport.pdf and MassDEP Office of Research and Standards (ORSG) for Manganese http://www.mass.gov/eea/agencies/massdep/water/drinking/manganese-in-drinking-water.html.

Maximum Contaminant Level or MCL: The highest level of a contaminant that is allowed in drinking water. MCLs are set as close to MCLGs (see below) as feasible using the best available technology.
